TALENT ACQUISITION | INTERVIEW HOME ASSIGNMENT

Glue Service Between Two Existing Systems — Forward Deployed Engineer Home Assignment

Format	Take-home build (~8–10 hours), followed by a 120 mins technical interview
Role	Forward Deployed Engineer (Senior)
Candidate	*Robert Militaru*
Return by	*26 octombrie 2026*

Role Context

Forward Deployed Engineer roles typically sit close to customers, translate ambiguous real-world needs into working software, and balance engineering quality with speed, pragmatism, and communication.

The Ask

A customer uses two systems or software-as-a-service products that do not integrate well, forcing manual work and errors. Design and build a small glue service that reconciles or synchronizes data between them, handling conflicts, retries, and partial failures.

Deliverables

You should submit a link to a Git repository (GitHub, GitLab, Bitbucket, or similar). The repository will be used as the main input for the following technical interview focused on walking through the design, implementation, assumptions, and possible extensions.

The submission should include runnable code, a README with setup and run instructions, assumptions, architecture overview, trade-offs, and known limitations. A short design note or diagram is optional but appreciated.

You should also include a short note describing the customer context you assumed and the value your solution would create. Please note that the brief is intentionally vague; you should make reasonable assumptions and document them.

You should bring your personal laptop for the technical interview; internet access will be provided on site.

Ground Rules

- **Scope and time investment**
  Expected effort is roughly 8–10 hours of focused work; the goal is not to build a production-grade system.

This assignment is for evaluation purposes only. It is not derived from an internal product requirement and will not be used as production code or incorporated directly into product work.

- **Depth over breadth**
  A small but coherent end-to-end slice is preferred over a wide but incomplete implementation. It is acceptable and encouraged to explicitly call out what was intentionally left out, and why.
- **Technology choices**
  You may use the languages, frameworks, and tools you know best. The evaluation is centered on clarity of design, code quality, reasoning, and trade-offs rather than alignment to a specific stack.
- **Use of AI**
  Use of AI tools is encouraged across ideation, design, coding, testing, and documentation. You should explain in the README where AI was used, how it was used, and where you deliberately chose not to rely on it.
- **Testing and reliability**
  Exhaustive test coverage is not required, but the solution should show how you think about correctness and reliability. A small but meaningful test set covering core behavior is preferred.
- **Observability and operability**
  The solution should include at least basic logging and minimal observability that fits the shape of the system. The goal is to understand how you would support and troubleshoot the system in practice.
- **Performance and scalability mindset**
  Numeric targets, where present, are indicative rather than strict requirements. What matters is whether you identify likely bottlenecks, have a sensible measurement strategy, and can explain how the design would scale.

This assignment is for evaluation purposes only. It is not derived from an internal product requirement and will not be used as production code or incorporated directly into product work.
